

CISC 839

Software Engineering of Usable Computing Systems

T.C. Nicholas Graham

<http://stl.cs.queensu.ca/~graham/cisc836>

Techniques for Stimulating Creative Design

- ⌘ Metaphor
- ⌘ Brainstorming

Metaphors

- ⌘ Something familiar to user from real world
- ⌘ Helps to structure user interface
- ⌘ Helps user understand structure, predict behaviour of user interface
 - ☒ ∴ Helps in developing mental model

Example Metaphors

- ⌘ Window
- ⌘ Copy/paste
- ⌘ Desktop

Window

Cut/Paste

Metaphors

- ⌘ Should help users to predict results of actions
 - ☑ Therefore important for metaphor to follow real life correctly
- ⌘ Alternative approach
 - ☑ Metaphor can be used in design, then stripped out of final product

Brainstorming

- ⌘ Method for group of people to come up with design ideas
- ⌘ Use large blackboard, large sheets of paper, etc.

Brainstorming

- ⌘ Allow people to throw out ideas
 - ☒ Record ideas
 - ☒ Most ideas will get thrown out, so don't worry about evaluating them
 - ☒ Sometimes a series of "dumb" ideas may lead to a good one
 - ☒ ...so don't be afraid to have "dumb" ideas!
 - ☒ Never criticize/put down ideas during brainstorming

Brainstorming

- ⌘ Can lead to quick, fluid development of ideas, creative thought

In-Class Exercise

- ⌘ Design a system for ordering pizza from your PC
- ⌘ Metaphor is:
 - ☒ Going for a trip to the zoo

User Interface Evaluation

Evaluating User Interfaces

- ⌘ Important to make evaluation early, continuous
- ⌘ Techniques:
 - ☒ Heuristic evaluation
 - ☒ Guidelines
 - ☒ Cognitive walkthrough
 - ☒ Usability testing (user observation)

Heuristic Evaluation

- ⌘ User interface specialists study user interface design in depth
- ⌘ Looking for known problems from their experience

Guidelines

- ⌘ Guidelines encode experience
- ⌘ In effect, allow non-specialists to perform their own heuristic evaluation
 - ☒ Guidelines help structure system evaluation by telling designers what problems to look for

Cognitive Walkthrough

- ⌘ Walk through interface in context of user trying to perform a task
 - ☒ Identify core tasks
 - ☒ Show how they would be accomplished by walking through interaction steps with user interface
- ⌘ Shows difficulties with task-action mapping
 - ☒ E.g. task hard to perform, task not supported at all
- ⌘ Helps identify areas where operations should be optimized

Approaches to Cognitive Walkthrough

- ⌘ Informal
 - ☒ Narrative scenario
 - ☒ write out steps followed by user in narrative prose
 - ☒ Low-fidelity prototype
 - ☒ cutouts of interface elements that can be manipulated by hand
 - ☒ Mockups
 - ☒ Simulations in Macromedia Director, Shockwave etc
- ⌘ Formal
 - ☒ Precise scenario
 - ☒ UML sequence diagram
 - ☒ Task-oriented specification
 - ☒ Refine ConcurTaskTree to action level
- ⌘ Formal approaches are great, but significant information can be gained from cheap, informal approaches

Usability Testing

- ⌘ Test usability of system by observing users
- ⌘ Users given specific task to accomplish
- ⌘ Observe to see what problems arise
- ⌘ Can be performed with low fidelity prototype or with real system
 - ☒ Trade off quality of feedback vs how early it can be obtained

Comparison of Four Approaches

- ⌘ UWE Project, HP [Jeffries et al., 1991]
- ⌘ Visual interface to Unix under X/Motif
- ⌘ Applied four methods separately to compare results
- ⌘ Error types
 - ☑ Consistency (25% of problems)
 - ☑ Recurring -- one time or recurring?
 - ☑ General -- affecting several parts of UI or specific to single part?

Heuristic Evaluation	Usability Testing	Guidelines	Cognitive Walkthrough
105 core errors identified – Identifies more problems – Identifies more serious problems – Low cost – Doesn't require implementation – Requires UI expertise – Requires several evaluators	31 core errors identified – Identifies serious, recurring problems – Avoids low priority problems – Requires UI expertise – High cost – Misses consistency problems – Requires implementation	35 core errors identified – Identifies recurring, general problems – Can be used by software developers – Does not require implementation – Misses some severe problems	35 core errors identified – Helps define user goals, assumption – Can be used by software developers – Does not require implementation – Needs task model – Tedious – Misses general, recurring problem

Kinds of Users for Testing [Booth]

- ⌘ Friendly users
 - ☑ Some technical knowledge
 - ☑ Can make suggestions that naïve users perhaps could not
- ⌘ Hostile users
 - ☑ People with no investment in system
 - ☑ May be useful at finding ways of breaking system
- ⌘ Simulating users
 - ☑ If progress of naïve users recorded, can be later replicated by designers
 - ☑ Form of informed cognitive walkthrough
 - ☑ Saves expense of live users for incremental modifications of system

10 Steps for Observing Users [Gomoll and Nicol]

- ⌘ Over all goal: observe real users using system, discover usability problems
- ⌘ Important that this be carried out in a controlled setting, as opposed to asking them for their opinion after the fact, or using a questionnaire

Step 1: Set up Observation

⌘ Write the tasks

- ☑ Design tasks for users to work through
- ☑ Should be real tasks, as motivated by task model
- ☑ Should be specific, phrased in terminology of user
- ☑ Focus on part of product under study

⌘ Recruit the users

- ☑ People with same experience level as user
- ☑ Should not be people familiar with the product

⌘ Create realistic situation

- ☑ Natural environment, free from interruptions
- ☑ Can use tape, video

Step 2: Describe Purpose of Observation

- ⌘ Emphasize you are testing the product, not the users
 - ☑ Want them to understand that if they run into problems, the problem is with the system, not them

Step 3: Tell user they can quit any time

- ⌘ Contributes to user's feeling that they are not being tested
- ⌘ Lowers stress
- ⌘ Basic ethical requirement on human experimentation

Step 4: Talk about, demonstrate equipment in room

- ⌘ Describe any recording, monitoring equipment
- ⌘ Removing mystery in process to lower anxiety of users

Step 5: Explain how to “think out loud”

- ⌘ As users are carrying out their task, they should say their thoughts out loud
 - ☒ This takes some practice - requires demonstration
- ⌘ Important for users to be comfortable
 - ☒ If they are nervous, they will not talk out loud

Step 6: Explain that you will not provide help

- ⌘ Users should be able to solve their problems on their own
- ⌘ Difficult for tester not to jump in!!
- ⌘ If they are really stuck, give threshold of 3 minutes, then give just enough help to proceed
- ⌘ Tell them “Even though I won’t be able to answer most of your questions, I’ll note them and answer them later”
 - ☒ And do!

Step 7: Describe tasks and introduce product

- ⌘ Give them written instructions
 - ☒ Walk through them - not enough to give them a piece of paper
- ⌘ Demonstrate anything that is not assumed prior knowledge
 - ☒ Do not demo the parts of the product you are trying to evaluate

Step 8: Begin observation

- ⌘ Ask if they have any questions
- ⌘ Begin once questions have been answered

Step 9: Conclude observation

⌘ After the users are finished

- ☒ explain what you were trying to find out
- ☒ answer any remaining questions (including the ones you wrote down while they were carrying out the task)
- ☒ discuss any interesting behaviours you want the user explain
- ☒ ask users for over all impressions

Step 10: Use the results

⌘ Remember to blame the system, not the user!!!
